## ABSTRACT

A pot experiment was carried out during the rabi season of 2015-2016 to study the interaction of Meloidogyne incognita and Colletotrichum lagenarium on ivy gourd. Experimental study revealed that, the dual inoculation treatments significantly decreased plant growth parameters were the treatment with M. incognita @ 1000J2 kg<sup>-1</sup> of soil and C. lagenarium @ 2% (w/w). The treatment with M. incognita @ 1000J2 kg<sup>-1</sup> of soil + C. lagenarium @ 2% (w/w) simultaneous inoculation was statistically superior in decreasing the plant growth parameters of ivy gourd. The number of galls, eggmasses and final nematode population were maximum in the treatment with M. incognita @ 1000 J2 per kg of soil. The maximum disease incidence was observed in the treatments with M. incognita @ 1000J2 kg<sup>-1</sup> of soil + C. lagenarium @ 2% (w/w) after 15 days of inoculation and simultaneous inoculation of M. incognita @ 1000J2 kg<sup>-1</sup> of soil + C. lagenarium @ 2% (w/w).

Keywords: Colletotrichum lagenarium, interaction, ivy gourd, Meloidogyne incognita and plant growth parameters

Ivy gourd, (Coccinea indica L.) is one of the most important nutritious vegetable and medicinal plants belong to the family Cucurbitaceae that has been recognized as a rich source of Beta-carotene, a major vitamin A precursor (Sinchaipanit et al., 2000; Sungpuag et al., 1999). It is also considered as a good source of iron, vitamin C, protein and fiber (Suresh-Babu and Rajan, 2001). A hundred grams (100 g) of ivy gourd fruit has a number of essential nutrients and 75KJ of energy. The root, stem, leaves and fruits of ivy gourds are used as medicine for controlling blood glucose levels in hyperglycemia. The leaves are very effective for treating diabetes as well as keeping sugar under control. It is also used for skin diseases such as ring worm, psoriasis itch, skin eruptions of small pox, small lesions of scabies etc. Fruits are effective for hypoglycemia, analgesia (reduces pain), tuberculosis, eczema, antipyretic, anti-inflammatory and hepato-protective (liver protective) condition. Stems are effective for treating expectorant, antispasmodic, asthma, bronchitis, GIT disturbances, urinary tract infection and skin diseases. Roots are effective against hypoglycemic, antidiabetic, skin diseases and joint pain. In India, a number of major and minor cucurbits are cultivated in several commercial cropping systems and they share about 5.6% of the total vegetable production of India. According to an FAO estimate, cucutbits were cultivated on about 4,290,000ha with the productivity of 10.52t ha<sup>-1</sup>.

Cucurbitaceous crops suffer from a number of pests and diseases which are caused by fungi, bacteria, virus and nematodes. Almost all cucurbitaceous crops may

Short communication Email: basumatarybinita3@gmail.com host of anthracnose disease. The infection was observed on leaves, stems, fruits and tendrils of snakegourd (Tricho- santhes anguina L.), ashgourd (Benincasa hispida Thunb. and Cogn), tinda or round-melon (Citrullus vulgaris var. fistulosus L.), watermelon (Citrullus lanatus Thunb. and Mansf.), bottlegourd (Lagenaria siceraria Mol and Standi.), muskmelon (Cucumis melo L.) and cucumber (C. sativus L.) (Prakash et al., 1974). Anthracnose caused 90 per cent losses in yield of bitter gourd and water melon (Sohi,1978). Among the different pests causing damage to cucurbit crops, plant parasitic root-knot nematodes (Meloidogyne spp.) are considered major limiting factors of successful crop cultivation. Besides causing direct damage to the plant as pathogens, nematodes play important and destructive roles in disease complexes, where they either act as incitants, aggravators or vectors. The importance of disease complexes has been a matter of serious concern from the time of first report by Atkinson (1892) when wilt resistant cotton became susceptible in the presence of root-knot nematode. In Konkan region, every year, this anthracnose-nematode complex caused heavy losses in yield of bitter gourd; yield losses to the tune of 58.86 per cent due to the combined attack of anthracnose and root-knot nematode (Jadhav et al., 2010) and 22.90-42.80 % due to sole infestation of root-knot nematode in bitter gourd have been documented (Khanna and Kumar, 2003). The presence of single pathogen may cause little damage while more than one may account for serious crop loss. Since fungal infection (Colletotrichum lagenarium) was frequently

encountered with most of the Cucurbitaceous crops (Prakash *et al.*,1974). Therefore an attempt was made to know the interrelationship, if any, between *M. incognita* and *C. lagenarium* of ivy gourd.

The experiment was carried out in the net house of Department of Nematology, Assam Agricultural University, Jorhat during the rabi season of 2015-2016. A pure culture of the fungus (C. lagenarium) was collected from the culture collection, Department of Plant Pathology, AAU, Jorhat. This culture of the fungus was maintained throughout the period of experimentation on PDA by periodically sub-culturing on fresh media and stored at 4°C. The purified C. lagenarium was multiplied on wheat-bran medium. For mass culture of fungus wheat-bran was soaked overnight and the water was allowed to drain out. About 200 g of wheat bran was put in to polypropylene bags. The bags were plugged with non-absorbent cotton. The medium was then autoclaved at 121°C and 15 lb pressure per square inch for 30 minutes. Sterilized media was inoculated with two mycelial discs (5 mm) cut out from the 5-6 days old culture of C. lagenarium and inoculated bags were incubated at  $28^{\circ}C \pm 1^{\circ}C$  for 20 days. Mass culture of C. lagenarium was inoculated @ 2% (w/w) and mixed with

the soil before planting or as per treatment combination. Local variety of ivy gourd terminal cuttings (semi hardwood cuttings) 15-20 cm long were planted at a depth of 5-6 cm deep in a 3kg capacity pot filled with sterilized pot mixture. After establishment of cuttings, freshly hatched 2<sup>nd</sup> stage juveniles of *M. incognita* were inoculated @ 1J2 g-1 of soil. The treatments included were: T1- Colletotrichum lagenarium @ 2% (w/w); T2-Meloidogyne incognita @ 1000 J2 kg<sup>-1</sup> of soil; T3- M. incognita @ 1000 J2 kg-1 of soil + C. lagenarium @ 2% (w/w) after 15 days of inoculation; T4- C. lagenarium @ 2% (w/w) + M. incognita @ 1000 J2 kg<sup>-1</sup> of soil after 15 days of inoculation; T5- M. incognita @ 1000 J2 kg-1 of soil + C. lagenarium @ 2% (w/w) simultaneous inoculation; T6- Uninoculated control. Each treatment was replicated ten times and pots were arranged in a completely randomized design. The experiments were terminated 60 days after inoculation. Observations were recorded on plant growth parameters (Shoot length, dry and fresh weight of shoot and root), number of galls, egg-masses per root system, nematode population in soil and disease incidence. The disease incidence per cent was calculated by using the following formula:

Disease incidence (DI %) = 
$$\frac{\text{No. of infected plant units}}{\text{Total number (healthy and infected) of units assessed}} \times 100$$

The result revealed that there was a significant reduction in the plant growth characters viz., shoot length, fresh weight of shoot, dry weight of shoot. These features were noticed in all treatments compaired to uninoculated controls (Table 1). Maximum percent reduction in shoot length (45.24), fresh weight of shoot (44.89), and dry weight of shoot (59.83) were recorded in the simultaneous inoculation of M. incognita @ 1000J2 kg<sup>-1</sup> of soil + C. lagenarium @ 2% (w/w) (T5), followed by M. incognita @ 1000J2 kg<sup>-1</sup> of soil + C. lagenarium @ 2% (w/w) after 15 days of inoculation (T3), M. incognita @ 1000J2 kg-1 of soil (T2), C. lagenarium @ 2% (w/w) + *M. incognita* @ 1000J2 kg<sup>-1</sup> of soil after 15 days of inoculation (T4) and C. lagenarium @ 2% (w/ w) (T1). Maximum per cent reduction in fresh weight of root and dry weight of root were recorded in the treatment C. lagenarium @ 2% (w/w) and maximum root weight (fresh and dry weight) was found in M. incognita @ 1000 J2 kg<sup>-1</sup> of soil followed by *M. incognita* @ 1000J2/ kg of soil + C. lagenarium @ 2% (w/w) after 15 days of inoculation, simultaneous inoculation of M. incognita @ 1000J2 kg<sup>-1</sup> of soil + C. lagenarium @ 2% (w/w) and *C. lagenarium* @ 2% (w/w) + *M. incognita* @ 1000J2 kg<sup>-1</sup> of soil after 15 days of inoculation compaired to uninoculated control. It was concluded that the number of galls (69.30) and eggmasses (33.80) and the final

population of *M. incognita* (413.24) was significantly higher in plants inoculated with *M. incognita* @ 1000J2/ kg of soil (T2). Fewer galls (34.10), eggmasses (16.70) and final population of *M. incognita* (262.67) were recorded in the plants inoculated with *C. lagenarium* @ 2% (w/w) + *M. incognita* @ 1000J2 kg<sup>-1</sup> of soil after 15 days of inoculation (T4) (Table 2). And the maximum disease incidence was recorded in simultaneous inoculation of *M. incognita* @ 1000J2 kg<sup>-1</sup> of soil + *C. lagenarium* @ 2% (w/w) (T5) and *M. incognita* @ 1000J2 kg<sup>-1</sup> of soil + *C. lagenarium* @ 2% (w/w) after 15 days of inoculation (T3). Both the treatments were statistically *at par*.

Studies on the interrelationship between *M. incognita* and *C. lagenarium* on plant growth parameters, number of gall, number of eggmasses, final population of *M. incognita* and disease incidence of ivy gourd were recorded. The maximum percent reduction in the plant growth parameters were recorded in the simultaneous inoculation of *M. incognita* @ 1000J2/kg of soil + *C. lagenarium* @ 2% (w/w) followed by *M. incognita* @ 1000J2 kg<sup>-1</sup> of soil + *C. lagenarium* @ 2% (w/w) after 15 days of inoculation, which was in accordance with the reports of earlier studies by Chandra *et al.* (2010) who reported that a decrease in shoot length (53%) in

bottle gourd was observed with a population of 10 nematodes per 500g of soil due to M. incognita alone. Maximum root weight (fresh and dry weight) was found in the treatment (T2) followed by the treatment (T3) compaired to uninoculated control. Cucurbits develop much larger galls due to spongy nature of the roots as a result root weight increased (Swarup et al., 1989). The results are in agreement with the findings of Catibog and Castillo (1975) on mungbean (Phaseolus aureus) who reported that with increase in inoculum levels of M. javanica, root weight of mungbean increases. The number of galls, eggmasses and nematode population was significantly higher in plants inoculated with the treatment T2 and fewer in the plants inoculated with the treatment T4. The findings are in agreement with Kakati and Mahanta (2013) who reported that maximum nematode population was observed in control plots of cucumber. And in the present study, the maximum disease incidence was recorded in the treatment with simultaneous inoculation of M. incognita @ 1000J2 kg<sup>-1</sup> of soil + C. lagenarium @ 2% (w/w) and M. incognita @ 1000J2 kg<sup>-1</sup> of soil + C. lagenarium @ 2% (w/w) after 15 days of inoculation, where both the treatments were statistically at par. This was in accordance with the reports of earlier studies by Jadhav et al. (2010) who reported that in the control plot of bitter gourd (anthracnose + root-knot infested plot) there was very high disease intensity (i.e 72.21 per cent). Anthracnose incidence caused by the fungus was maximum when inoculated either simultaneously or when nematodes were followed by fungus. It is evident that the prior invasion of nematode in to the roots made the host more suitable for fungal infection by providing a metabolically rich substrate. Alternatively or in addition nematodes might modify the rhizosphere to favour the fungal growth (Owens and Specht, 1966).

The present study demonstrate the interrelationship between *M. incognita* and *C. lagenarium* of ivy gourd. The development of a successful strategy to manage root-knot nematode and anthracnose fungus disease complex should depend primarily on integrated disease management including methods to suppress the population of both pathogens in field soils.
